A Multidisciplinary Rehabilitation Approach for Writer’s Cramp: A Case Study

Tripathi D R¹, Kumar Amod², Talele Mahesh³, Singh Suryabhan⁴

Abstract

A 61 year-old male was referred from neurology to PMR department RML hospital, New Delhi, with difficulty in writing for 2 years prior to consultation. Initially difficulty in writing which is accompanied with pain after prolonged writing. Also he noticed tremor and stiffness while writing. Disability progressed and he was unable to write even a few words legibly and cannot hold object (spoon) which leads to anxiety and dependency.

When the patient was examined at PMR OPD, EMG/NCV study was advised, which showed normal sensory and motor nerve functions.

The present treatment involved the use of a multidisciplinary therapeutic approach with Physical Medicine and Rehabilitation Specialist, Clinical psychologist and Occupational Therapist which gave us satisfactory results within 6-8 months. The findings in this case is very encouraging and studies with large sample sizes can be considered for further conclusive evidence on the treatment of writer’s cramp.

Keywords: Writer’s cramp, multidisciplinary approach.

Introduction:

Writer’s cramp is classified as an occupational neurosis and is one of a large group of functional motor disorders. Writer’s cramp is characterised by muscular spasm of the fingers and hand of the writing arm, often spreading to the muscles of the lower and upper arm and to the shoulder girdle with consequent inco-ordination and discomfort, variously described as fatigue, weakness, stiffness or pain, when attempting to write. Accompanying tremor and jerking of the limb while writing. The pen is then grasped more and more tightly and the hand writing becomes progressively more illegible up to a stage when writing may become impossible.

Epidemiology: It is more common in males and appears most often in the third and the fourth decade. Those involved in constant writing typing and key board telegraphy have higher incidence. In Australian study: prevalence of 14% for writer’s cramp in a group of 516 male telegraphists¹. In an Indian study Mahendru et al² (1981) have reported a prevalence of 5.4 per thousand among office workers.

Case Report:

Case: A 51 years old male patient referred from neurology department to PMR department of Dr. RML Hospital who was clinically normal except difficulty in writing for 2 years prior to consultation. Initially he had difficulty in writing which is accompanied with pain after prolonged writing, also he noticed tremor and stiffness while writing. Disability progressed and he was unable to write even a few words legibly and could not hold objects (spoon) which leads to anxiety and dependency. There is no history of similar episode in the past. Family history and drug history is not significant. No H/O of HTN, DM, CVA, AVM Basal ganglia or cortical tumour. EMG/NCV study was advised, which showed normal sensory and motor nerve functions.
General physical examination: Assumption of dystonic posture during writing (semiflex position of finger with hyperextension of wrist) was noted. Tremor was present when hand is outstretched. There is no sensory and motor deficit. Biochemical analysis and MRI is normal.

Pathophysiology: At present three general lines of work that may indicate physiological substrate for dystonia. All three are persuasive and it is not clear whether they are related to each other or whether one is more fundamental than the other.

Loss of inhibition - Hallett, 2004 found the principal finding in focal dystonia is that of loss of inhibition. Excessive movement causing long bursts of EMG activity, cocontraction of antagonist muscle and overflow of activity into muscle not intendend for task.

Abnormal plasticity - Repetitive activity over long period seems to be a trigger for its development (an animal model support this idea).

Abnormal sensory function - Clinically not demonstrable but can be demonstrate by somatosensory evoked potential (SEP) testing.

The most acceptable hypothesis for the genesis of writer’s cramp is that it starts as a symptom of anxiety neurosis in people whose main occupation involves the use of fingers.

Treatment plan (Figs 1-4): The present paper describes the method of treatment usually followed in our department in the management of writer’s cramp (Figs 5 and 6) combining the psychologcical and occupational therapy regimes.

1) Jacobson relaxation exercises, 2) Desensitisation, 3) Retraining.

Treatment duration
- Each session for 5 days and time duration of each session is 40 minutes.
- Per day 2 sessions carried out one sessions with Occupational therapist and second sessions at home.

Treatment outcome
Pain, tremor and spasm is symptom free. Patient writing speed is 5-6 words per minute. Symptom free writing more than 200 words and symptom free period 2 years.
The main purpose of this paper is to say that in our treatment plan [the combined approach of i) relaxation exercises ii) desensitization and iii) retraining exercises] usually followed in our department is very useful patients presenting with writer’s cramp (traditionally known to be refractory to several therapeutic approaches) as the duration of treatment is less and no recurrence has been found.. No attempt was made to separate the treatment components. Nor is any attempt made to make a comparative evaluation of this treatment plan. Several treatment modalities have been tried by various
workers. The view that radicular irritation of cervical spine leads to treatments like galvanic and faradic stimulation, electrified pens, cortisone, ultrasonic therapy and cervical traction. But these treatments were of no significant benefit. Some neurologists, viewing the disturbance as being related to extrapyramidal disorders, have used antiparkinsonism drug, with poor success. Some psychiatrists viewed it as a hysterical symptom while others viewed it as an obsessive neurosis. Sedation, hypnosis and psychodrama were tried unsuccessfully.

A psychosomatic formulation states that the act of writing is a refined and delicate motor skill, incompatible with grosser postures of the upper limb, associated with emotional states like anger. When such a state affects a person chronically or arises specifically in relation to the act of writing, it may progressively distort the writing as the person makes a succession of attempts to overcome the difficulty. Crisp and Moldofsky reported the usefulness of relaxation and re-educative techniques along with psychotherapy in the treatment of writer’s cramps. Janet et al. 1925 was advocating a complex programme of exercises to strengthen the extensor of the hand followed by teaching the patient to write with the hand supinated to encourage activity of the extensor muscles and to discourage excessive flexion of the digits. Then, to redevelop accurate writing movements of the hand, such shaping devices as special keyboards and pigeonholes were introduced.

More recently relaxation has been advocated in the treatment of the condition and in one study it was used in conjunction with a programme in which the individual was taught to write again, using in the first instance a pen with a wide, soft, felt nib for the drawing of simple shapes and progressing to adult script with a normal pen. While general muscular skeletal relaxation was the aim, particular emphasis in this respect was placed on the upper limbs.

**Conclusion:**

It’s a fascinating condition. Recent findings have been useful in suggesting new therapeutic approaches to the disorder. Present case study demonstrate that writer cramp can be treated using a multidisciplinary approach. Finding in this case is very encouraging and study with large sample size is being done for further conclusive evidence on the treatment of writer’s cramp.
